

Django REST Framework

Explanation:

1. **CSRF Token:** Django requires a CSRF token for POST requests when using session authentication to prevent cross-site request forgery. The `getCookie` function retrieves it from the `csrftoken` cookie (which Django sets automatically, often on pages rendered with `{% csrf_token %}`). This token is sent in the `X-CSRFToken` header.
2. **credentials: 'include':** This is essential for `SessionAuthentication`. It tells the browser to include any cookies (specifically the `sessionid` cookie) associated with the domain in the fetch request. DRF uses this cookie to identify the `request.user`.
3. **Content-Type: 'application/json':** Tells the server that the request body contains JSON data.
4. **body: JSON.stringify(noteData):** Converts the JavaScript `noteData` object into a JSON string to be sent in the request body.
5. **No User ID in Body:** Notice `author` is *not* included in `noteData`. Your backend's `perform_create` method handles associating the note with the authenticated user (`self.request.user`).
